Abstract—A three-dimensional (3-D) geometrical propagation model for multi-input-multi-output (MIMO) mobile-to-mobile (M-to-M) communications is proposed. Based on the geometrical model, a 3-D reference model for MIMO M-to-M multipath fading channels is proposed. From the reference model, a closed-form joint space-time correlation function is derived for a 3-D non-isotropic scattering environment and it is shown that many existing correlation functions are special cases of the derived space-time correlation function.

I. INTRODUCTION

Mobile-to-mobile (M-to-M) communications play an important role in mobile ad-hoc wireless networks, intelligent transportation systems, and relay-based cellular networks. M-to-M communication systems are equipped with low elevation antennas and have both the transmitter (T_x) and receiver (R_x) in motion. To successfully design M-to-M systems, it is necessary to have a detailed knowledge of the multipath fading channel and its statistical properties. Early studies of single-input-single-output (SISO) M-to-M Rayleigh fading channels are reported in [1], [2]. They showed that the received envelope of M-to-M channels is Rayleigh faded under non line-of-sight conditions, but the statistical properties differ from fixed-to-mobile (F-to-M) channels. They also proposed a reference model for SISO M-to-M Rayleigh fading channels. Simulation models for SISO M-to-M channels have been proposed in [3]-[5]. Recently, the reference models for narrow-band multi-input-multiples-output (MIMO) M-to-M channels have been proposed in [6], [7]. Simulation models for MIMO M-to-M channels have been proposed in [8], [9].

All previously reported models assume that the field incident on the (T_x) or (R_x) antenna is composed of a number of waves travelling only in the horizontal plane. This assumption is acceptable only for certain environments, e.g., rural areas. However, it does not seem appropriate for urban environment in which the (T_x) and (R_x) antenna arrays are often located in close proximity to and lower than surrounding buildings. Scattered waves may propagate by diffraction from the tops of buildings down to the street, and thus not necessarily travel horizontally. Hence, this paper proposes a three-dimensional (3-D) reference model for MIMO M-to-M multipath fading channels. To describe our 3-D reference model, we first introduce a 3-D geometrical model for MIMO M-to-M channels, referred to as a “two-cylinder” model. This model is extension of the one-cylinder model for F-to-M channels proposed in [10], [11]. By taking into account local scattering around both the T_x and R_x and by including mobility of both the T_x and R_x, we obtain our two-cylinder model. From the 3-D reference model, we derive a closed-form joint space-time correlation function for a 3-D non-isotropic scattering environment. Furthermore, we show that many existing correlation functions are special cases of our 3-D MIMO M-to-M space-time correlation function. Finally, we present some simulation results to verify theoretical derivations.

The remainder of the paper is organized as follows. Section II introduces a geometrical two-cylinder model. Section III presents a 3-D reference model for MIMO M-to-M channels. Section IV derives the closed-form joint space-time correlation function for 3-D non-isotropic scattering. Section V presents some simulation results to verify theoretical derivations. Finally, Section VI provides some concluding remarks.

II. A GEOMETRICAL TWO-CYLINDER MODEL

In this section, we introduce a 3-D geometrical model for MIMO M-to-M channels, called a two-cylinder model. We consider a narrow-band MIMO communication system with \( L_t \) transmit and \( L_r \) receive omnidirectional antenna elements. It is assumed that both the T_x and R_x are in motion and equipped with low elevation antennas. The radio propagation environment is characterized by 3-D scattering with non-line-of-sight (NLoS) propagation conditions between the T_x and R_x.

The two-cylinder model is an extension of the one-cylinder model for F-to-M channels proposed in [10], [11]. By taking into account local scattering around both the T_x and R_x and by including mobility of both the T_x and R_x, we obtain our two-cylinder model.

Fig. 1 shows the two-cylinder model for a MIMO M-to-M channel with \( L_t = L_r = 2 \) antenna elements. The two-cylinder model defines two cylinders, one around the T_x and another around the R_x, as shown in Fig. 1. Around the transmitter, \( M \) fixed omnidirectional scatterers lie on a surface of a cylinder of radius \( R_t \), and the \( m^{th} \) transmit scatterer is denoted by \( S_T^{(m)} \). Similarly, around the receiver, \( N \) fixed omnidirectional scatterers lie on the surface of a cylinder of radius \( R_r \), and...
the \( n^{th} \) receive scatterer is denoted by \( S_R^{(n)} \). The distance between the centers of the \( T_x \) and \( R_x \) cylinders is \( D \). It is assumed that the radii \( R_t \) and \( R_r \) are much smaller than the distance \( D \), i.e., \( \max\{R_t, R_r\} \ll D \). The spacing between antenna elements at the \( T_x \) and \( R_x \) is denoted by \( d_T \) and \( d_R \), respectively. It is assumed that \( d_T \) and \( d_R \) are much smaller than the radii \( R_t \) and \( R_r \), i.e., \( \max\{d_T, d_R\} \ll \min\{R_t, R_r\} \). Angles \( \theta_T \) and \( \theta_R \) describe the orientation of the \( T_x \) and \( R_x \) antenna array in the \( x-y \) plane, respectively, relative to the \( x \)-axis. Similarly, angles \( \psi_T \) and \( \psi_R \) describe the elevation of the \( T_x \)’s antenna array and the \( R_x \)’s antenna array relative to the \( x-y \) plane, respectively. The \( T_x \) and \( R_x \) are moving with speeds \( v_T \) and \( v_R \) in directions described by angles \( \gamma_T \) and \( \gamma_R \), respectively. The symbols \( \alpha_T^{(m)} \) and \( \alpha_R^{(n)} \) denote the azimuth angle of departure (A AoD) and the azimuth angle of arrival (A AoA), respectively. Similarly, the symbols \( \beta_T^{(m)} \) and \( \beta_R^{(n)} \) denote the elevation angle of departure (E AoD) and the elevation angle of arrival (E AoA), respectively. Finally, the symbols \( \epsilon_{pm} \), \( \epsilon_{mn} \), and \( \epsilon_{nq} \) denote distances \( A_T^{(p)} - S_T^{(m)} \), \( S_T^{(m)} - S_R^{(n)} \), and \( S_R^{(n)} - A_R^{(q)} \), respectively, as shown in Fig. 1.

\[ h_{pq}(t) = \lim_{M,N \to \infty} \frac{1}{M N} \sum_{m=1}^{M} \sum_{n=1}^{N} e^{-j \frac{2 \pi}{\lambda} (\epsilon_{pm} + \epsilon_{mn} + \epsilon_{nq}) + j \phi_{mn}} e^{j 2 \pi f_{\text{fmax}}(\alpha_T^{(m)} - \gamma_T) \cos \beta_T^{(m)} + j f_{\text{fmax}}(\alpha_R^{(n)} - \gamma_R) \cos \beta_R^{(n)}} \]

where \( f_{\text{fmax}} = v_T/\lambda \) and \( f_{\text{fmax}} = v_R/\lambda \) are the maximum Doppler frequencies associated with the \( T_x \) and \( R_x \), respectively, and \( \lambda \) is the carrier wavelength. It is assumed that the angles of departures (AAoDs and EAoDs) and the angles of arrivals (AAoAs and EAoAs) are random variables, and that the angles of departure are independent from the angles of arrival. Additionally, it is assumed that the phases \( \phi_{mn} \) are random variables uniformly distributed on the interval \([-\pi, \pi]\) and independent form the angles of departures and the angles of arrivals.

The distances \( \epsilon_{pm}, \epsilon_{mn}, \) and \( \epsilon_{nq} \) can be expressed as functions of the random variables \( \alpha_T^{(m)}, \alpha_R^{(n)}, \beta_T^{(m)}, \) and \( \beta_R^{(n)} \) as follows:

\[
\epsilon_{pm} \approx R_t - \frac{d_T}{2} \sin \psi_T \sin \alpha_T^{(m)} -
\]

\[
\frac{d_T}{2} \cos \psi_T \cos \alpha_T^{(m)} \left( \cos \theta_T \sin \alpha_T^{(m)} + \sin \theta_T \sin \alpha_T^{(m)} \right),
\]

\[
\epsilon_{nq} \approx R_r - \frac{d_R}{2} \sin \psi_R \sin \alpha_R^{(n)} -
\]

\[
\frac{d_R}{2} \cos \psi_R \cos \alpha_R^{(n)} \left( \cos \theta_R \sin \alpha_R^{(n)} + \sin \theta_R \sin \alpha_R^{(n)} \right),
\]

\[
\epsilon_{mn} \approx D.
\]

Derivations of expressions (2) - (4) are omitted for brevity.

Using (2) - (4), the complex faded envelope of the link \( A_T^{(p)} - A_R^{(q)} \) can be rewritten as

\[
\begin{align*}
\sum_{m,n=1}^{M,N} a_{p,m} b_{n,q} e^{j \phi_{mn} + j \phi_0} \\
\end{align*}
\]

where \( \phi_0 = -2\pi (R_t + R_r + D)/\lambda \) and parameters \( a_{p,m} \) and \( b_{n,q} \) are defined as

\[
\begin{align*}
a_{p,m} &= e^{j \frac{2 \pi}{\lambda} d_T \sin \psi_T \sin \beta_T^{(m)}} \\
&= e^{j \frac{2 \pi}{\lambda} d_T \sin \psi_T \cos \alpha_T^{(m)} \cos \beta_T^{(m)} + j \phi_0},
\end{align*}
\]

\[
\begin{align*}
b_{n,q} &= e^{j \frac{2 \pi}{\lambda} d_R \sin \psi_R \sin \beta_R^{(n)}} \\
&= e^{j \frac{2 \pi}{\lambda} d_R \sin \psi_R \cos \beta_R^{(n)} \cos \alpha_R^{(n)} + j \phi_0}.
\end{align*}
\]

Note that the constant phase \( \phi_0 \) can be set to zero without loss of generality, because it does not affect statistical properties of the model.

III. A 3-D REFERENCE MODEL FOR MIMO MOBILE-TO-MOBILE CHANNELS

In this section, we derive a reference model for MIMO M-to-M multipath fading channels. The starting point is the two-cylinder model shown in Fig. 1. From the two-cylinder model, we observe that the waves from the \( T_x \) antenna elements first arrive at the scatterers located on the \( T_x \) cylinder. Considering these fixed scatterers as “virtual base-stations” (VBS), the communication link from each VBS to the \( R_x \) is modelled as a 3-D F-to-M link. The signals from each VBS arrive at the \( R_x \) antenna from all directions and with equal power due to 3-D scattering around the \( R_x \).

The MIMO channel is described by an \( L_r \times L_t \) matrix \( H(t) = [h_{ij}(t)]_{L_r \times L_t} \) of complex low-pass faded envelopes.
IV. SPACE-TIME CORRELATION FUNCTION OF THE 3-D REFERENCE MODEL

Assuming a 3-D non-isotropic scattering environment, we now derive the space-time correlation function of the complex faded envelope described in (5). The normalized space-time correlation function between two complex faded envelopes $h_{pq}(t)$ and $h_{pq}(t')$ is defined as

$$R_{pq,pq}[d_T, d_R, \tau] = \frac{E[h_{pq}(t)h_{pq}^*(t + \tau)]}{\sqrt{E[h_{pq}^+(t)]E[h_{pq}^*(t')]}}$$

where $(\cdot)^*$ denotes complex conjugate operation, $E[\cdot]$ is the statistical expectation operator, $p, q \in \{1, \ldots, L_r\}$, and $t \in \{1, \ldots, L_r\}$. Using (5) and (8), the space-time correlation function can be written as

$$R_{pq,pq}[d_T, d_R, \tau] = \lim_{M, N \to \infty} \frac{1}{MN} \sum_{m,n=1}^{M,N} E[d_{pq} d_{pq}^* h_{pq}^* h_{pq}] e^{-j2\pi f_{TM} \cos(\alpha_T - \gamma_T) \cos(\beta_T - \gamma_T) \cos(\beta_T - \gamma_T)}$$

Since the number of local scatterers in the reference model described in Section III is infinite, the discrete $\alpha_T$, $\beta_T$, $\alpha_R$, $\beta_R$ with probability density functions (pdf) $f(\alpha_T)$, $f(\beta_T)$, $f(\alpha_R)$, and $f(\beta_R)$, respectively. Here, (9) can be rewritten as

$$R_{pq,pq}[d_T, d_R, \tau] = \lim_{M, N \to \infty} \frac{1}{MN} \sum_{m,n=1}^{M,N} E[d_{pq} d_{pq}^* h_{pq}^* h_{pq}] e^{-j2\pi f_{TM} \cos(\alpha_T - \gamma_T) \cos(\beta_T - \gamma_T) \cos(\beta_T - \gamma_T)}$$

where $\beta_T$ and $\beta_R$ are the maximum elevation angles of the scatterers around the $T_x$ and $R_x$, respectively.

Several different scatterer distributions, such as uniform, Gaussian, Laplacian, and von Mises, are used in prior work to characterize the continuous random variables $\alpha_T$ and $\alpha_R$. In this paper, we use the von Mises pdf because it approximates many of the previously mentioned distributions and leads to closed-form solutions for many useful situations. The von Mises pdf is defined as [12]

$$f(\theta) = \frac{1}{2\pi I_0(k)} \exp[k \cos(\theta - \mu)]$$

where $\theta \in [-\pi, \pi]$, $I_0(\cdot)$ is the zeroth-order modified Bessel function of the first kind, $\mu \in [-\pi, \pi]$ is the mean angle at which the scatterers are distributed in the $x$-$y$ plane, and $k$ controls the spread of scatterers around the mean. To characterize the continuous random variables $\beta_T$ and $\beta_R$, we use the pdf [11]

$$f(\varphi) = \begin{cases} \frac{\pi}{4|\varphi_m|} \cos \left( \frac{\pi}{2} \frac{\varphi_m}{|\varphi_m|} \right) , & |\varphi_m| \leq \varphi_m \leq \frac{\pi}{2} \\ 0 , & \text{otherwise} \end{cases}$$

where $\varphi_m$ is the maximum elevation angle and takes values in the range $10^\circ \leq \varphi_m \leq 20^\circ$ [13].

By grouping the terms in (10) into those containing $\alpha_T$ and $\beta_T$ and those containing $\alpha_R$ and $\beta_R$, the integrals in (10) reduce to the product of two double integrals, because the random variables $\alpha_T$ and $\beta_T$ are independent from the random variables $\alpha_R$ and $\beta_R$. By denoting the von Mises pdf for the $T_x$ and $R_x$ azimuth angles as $f(\alpha_T) = \exp[k_T \cos(\alpha_T - \mu_T)]/2\pi I_0(k_T)$ and $f(\alpha_R) = \exp[k_R \cos(\alpha_R - \mu_R)]/2\pi I_0(k_R)$, respectively, and by denoting the pdf for the $T_x$ and $R_x$ elevation angles as $f(\beta_T) = \pi \cos(\pi \beta_T/(2\beta_R))/(4\beta_R)$ and $f(\beta_R) = \pi \cos(\pi \beta_T/(2\beta_R))/(4\beta_R)$, respectively, the space-time correlation function becomes

$$R_{pq,pq}[d_T, d_R, \tau] = R_{p,p}^T[d_T, \tau] R_{q,q}^R[d_R, \tau]$$

where $g(\alpha_T, \beta_T)$ and $g(\alpha_R, \beta_R)$ are defined as

$$g(\alpha_T, \beta_T) = \frac{\pi}{4|\beta_T|} \cos \left( \frac{\pi}{2} \frac{\beta_T}{|\beta_T|} \right) \exp[k \cos(\alpha_T - \mu_T)]$$

$$g(\alpha_R, \beta_R) = \frac{\pi}{4|\beta_R|} \cos \left( \frac{\pi}{2} \frac{\beta_R}{|\beta_R|} \right) \exp[k \cos(\alpha_R - \mu_R)]$$

respectively. Using trigonometric transformations and the equality $\int_{-\pi}^{\pi} \exp(a \sin x + b \cos x) \, dx = 2 \pi I_0(\sqrt{a^2 + b^2})$ [14, eq. 3.384-4], the space-time correlation function becomes

$$R_{pq,pq}[d_T, d_R, \tau] = \frac{\pi}{4|\beta_T|} \exp[k \cos(\alpha_T - \mu_T)]$$

where parameters $x, y, z,$ and $w$ are

$$x = j2\pi d_T / \lambda - j2\pi f_{TM} \cos \gamma_T + k_T \cos \mu_T / \cos \beta_T$$

$$y = j2\pi d_R / \lambda - j2\pi f_{TM} \cos \gamma_R + k_R \cos \mu_R / \cos \beta_R$$

$$z = j2\pi d_T / \lambda - j2\pi f_{TM} \cos \gamma_T + k_T \cos \mu_T / \cos \beta_T$$

$$w = j2\pi d_R / \lambda - j2\pi f_{TM} \cos \gamma_R + k_R \cos \mu_R / \cos \beta_R$$

and where $d_T = d_T \cos \theta_T \cos \psi_T$, $d_T = d_T \sin \theta_T \cos \psi_T$, $d_R = d_R \cos \theta_R \cos \psi_R$, and $d_R = d_R \sin \theta_R \cos \psi_R$.

To obtain the space-time correlation function for the 3-D MIMO M-to-M system, the integrals in (16) have to be evaluated numerically, because they do not have closed-form solutions. Since $\beta_T$ and $\beta_R$ are small angles, i.e., $|\beta_T| \leq 10^\circ$, $|\beta_R| \leq 20^\circ$, using approximations $\cos \beta_T$, $\cos \beta_R \approx 1$, $\sin \beta_T \approx \beta_T$, and
\[
\sin \beta_R \approx \beta_R, \text{ the space-time correlation function can be approximated as}
\]
\[
R_{pq, \beta \tilde{d}}(x, y, \tau) = R_{pq, \beta \tilde{d}}(x, y, \tau) R_{q, \beta \tilde{d}}(y, x, \tau) \approx \frac{I_0(\sqrt{x^2 + y^2})}{I_0(\xi)} \int_{-\beta_R \Delta \beta_R}^{\beta_R \Delta \beta_R} \cos \left( \frac{\beta_R}{2} \right) e^{i \frac{2\pi}{\lambda} x \sin \beta_T \tau \beta_T} d \beta_T
\]
\[
= \frac{I_0(\sqrt{x^2 + y^2})}{I_0(\xi)} \int_{-\beta_R \Delta \beta_R}^{\beta_R \Delta \beta_R} \cos \left( \frac{\beta_R}{2} \right) e^{i \frac{2\pi}{\lambda} y \sin \beta_T \tau \beta_T} d \beta_T,
\]
where parameters \(x, y, z,\) and \(w\) are

\[
x_1 = j2\pi \rho d_T / \lambda - j2\pi f_T \max \cos \gamma_T + k_T \cos \mu_T,
\]
\[
y_1 = j2\pi \rho d_R / \lambda - j2\pi f_T \max \sin \gamma_T + k_T \sin \mu_T,
\]
\[
z_1 = j2\pi \rho d_T / \lambda - j2\pi f_T \max \cos \gamma_R + k_T \cos \mu_R,
\]
\[
w_1 = j2\pi \rho d_R / \lambda - j2\pi f_T \max \sin \gamma_R + k_T \sin \mu_R.
\]

Finally, solving the integrals in (17), the space-time correlation function becomes

\[
R_{pq, \beta \tilde{d}}(x, y, \tau) \approx \frac{I_0(\sqrt{x^2 + y^2})}{I_0(\xi)} \cos \left( \frac{2\pi}{\lambda} \beta_T \max d_T \sin \psi_T \right) \cos \left( \frac{2\pi}{\lambda} \beta_R \max d_R \sin \psi_R \right)
\]
\[
\frac{I_0(\xi)}{I_0(\xi)} \int_0^{\pi \xi \max} \cos \left( \frac{2\pi}{\lambda} \beta_T \max d_T \sin \psi_T \right) \cos \left( \frac{2\pi}{\lambda} \beta_R \max d_R \sin \psi_R \right) d \psi_T
\]
\[
\frac{I_0(\xi)}{I_0(\xi)} \int_0^{\pi \xi \max} \cos \left( \frac{2\pi}{\lambda} \beta_T \max d_T \sin \psi_T \right) \cos \left( \frac{2\pi}{\lambda} \beta_R \max d_R \sin \psi_R \right) d \psi_R.
\]

Many existing correlation functions are special cases of the 3-D MIMO M-to-M space-time correlation function in (19). The simplest special case of (19) is Clark’s temporal correlation function \(J_0(2\pi f_T \max \tau)\) [15], obtained for \(K_T = \beta_T \max = 0\) (2-D isotropic scattering around \(R_x\)), \(f_T \max = 0\) (stationary \(T_x\), no scattering), and \(d_T = d_R = 0\) (single-antenna \(T_x\) and \(R_x\)), where \(J_0(\cdot)\) is the first kind zeroth-order Bessel function. Expressions for other space-time correlation functions based on the one-ring model [16], [17] and based on the one-cylinder model [11], [18] can be similarly obtained.

The temporal correlation function for M-to-M channels, assuming 2-D isotropic scattering, \(J_0(2\pi f_T \max \tau)\) [1], is obtained for \(K_T = K_R = 0\), \(d_T = d_R = 0\), and \(\beta_T \max = \beta_R \max = 0\). Similarly, assuming 2-D isotropic scattering, the spatial correlation function for M-to-M channel \(J_0(2\pi d_T / \lambda) J_0(2\pi d_R / \lambda)\) [19] is obtained for \(K_T = K_R = 0\), \(\beta_T \max = \beta_R \max = 0\) and \(\tau = 0\). Finally, the space-time correlation function for M-to-M channels, assuming 2-D non-isotropic scattering, \(I_0(\sqrt{x^2 + y^2}) I_0(\sqrt{z^2 + w^2}) / (I_0(\xi) I_0(\xi))\) [7] is obtained for \(\beta_T \max = \beta_R \max = 0\).

V. SIMULATION RESULTS

In this section, we present some simulation results to verify theoretical derivations. In all simulations, we use a normalized sampling period \(f_T \max T_x = 0.01\) (\(f_T \max = f_T \max\) are the maximum Doppler frequencies and \(T_x\) is the sampling period). Unless indicated otherwise, the number of transmit and receive antennas is set to \(L_t = L_r = 2\).

To validate approximations used to obtain the space-time correlation function in (19), we compare it with the numerically obtained space-time correlation function in (16). Fig. 2 shows good agreement between the space-time correlation functions in (16) and (19). The parameters used to obtain curves in Fig. 2 are \(d_T = d_R = 0.5\lambda, \beta_T \max = \beta_R \max = 20^\circ, \theta_T = \theta_R = \pi/4, \psi_T = \psi_R = 2\pi/3, \gamma_T = 20^\circ, \gamma_R = 40^\circ, \) and \(k_T = k_R = 0\).

The 2-D space-time correlation functions for M-to-M channels [6]-[9] suggest that two vertically placed antennas are completely correlated and no diversity gain is available. However, the 3-D space-time correlation function shows that vertically placed antennas can have small correlations and provide considerable diversity gain. To illustrate this, Fig. 3 shows the space-time correlation functions of two vertically spaced antennas at the \(T_x\) for several maximum elevation angles \(\beta_T \max\). Other parameters used to obtain curves in Fig. 3 are \(L_t = 1, \theta_T = \theta_R = 0, \psi_T = \pi/2, \psi_R = 0, \gamma_T = \gamma_R = 0, \) and \(k_T = k_R = 0\). As the maximum elevation angle \(\beta_T \max\) increases from 1° to 20°, the correlation between the two antennas reduces dramatically.

![Fig. 2. Comparison of the normalized space-time correlation functions in (16) and (19).](image1)

![Fig. 3. The normalized space-time correlation functions of two vertically spaced antennas at the \(T_x\) for several maximum elevation angles \(\beta_T \max\).](image2)
ergodic channel capacity (in bit/s/Hz) of a stochastic MIMO channel, under an average transmit power constraint, is given by [20]

\[ E[C(t)] = E \left[ \log_2 \det \left( \mathbf{I}_{L_t} + \frac{\rho}{L_t} \mathbf{H}(t) \mathbf{H}^H(t) \right) \right], \quad (20) \]

where it is assumed that \( L_t \geq L_r \), the transmitter has no channel knowledge, and the receiver has perfect channel knowledge. In (20), \( \mathbf{H}(t) = [h_{ij}(t)]_{L_r \times L_t} \) is the \( L_r \times L_t \) matrix of complex faded envelopes, \( (\cdot)^H \) denotes the transpose conjugate operation, \( \det(\cdot) \) denotes the matrix determinant, \( \mathbf{I}_{L_t} \) is the \( L_t \times L_t \) identity matrix, and \( \rho \) is the average signal-to-noise ratio (SNR). The channel matrix \( \mathbf{H} \) can be generated as a product of the white channel matrix and the square root of desired correlation matrix [21], i.e.,

\[ \mathbf{H} = (\mathbf{R}_T[d_T, 0])^{1/2} \mathbf{G}(\mathbf{R}_R[d_R, 0])^{T/2}, \quad (21) \]

where \( \mathbf{G} \) is an \( L_t \times L_r \) stochastic matrix with complex Gaussian i.i.d. entries, \( (\cdot)^{1/2} \) denotes the matrix square root operation, and \( \mathbf{R}_T[d_T, 0] \) and \( \mathbf{R}_R[d_R, 0] \) are the \( L_t \times L_t \) transmit correlation matrix and the \( L_r \times L_r \) receive correlation matrix, respectively. The elements of matrices \( \mathbf{R}_T[d_T, 0] \) and \( \mathbf{R}_R[d_R, 0] \) are obtained using (19). Fig. 4 shows the ergodic capacity against SNR, for several linear antenna arrays (\( L_t = L_r = 2, L_t = L_r = 4, \) and \( L_t = L_r = 6 \)). Parameters used to obtain curves in Fig. 4 are \( \theta_T = \theta_R = \pi/4, \psi_T = \psi_R = \pi/6, \gamma_T = 0 \) and \( \gamma_R = 20^\circ, \beta_{TM} = \beta_{Im} = 15^\circ, k_T = k_R = 5, \mu_T = \pi/2, \) and \( \mu_R = 3\pi/2 \). The spacing between two adjacent antenna elements at the Tx and Rx is chosen to be 0.5\( \lambda \).

VI. CONCLUSIONS

In this paper, a two-cylinder geometrical propagation model is introduced. Based on this geometrical model, a 3-D reference model for MIMO M-to-M fading channels is proposed. From the reference model, a closed-form joint space-time correlation function for 3-D non-isotropic scattering environment is derived. It is shown that many existing correlation functions are special cases of our 3-D MIMO M-to-M space-time correlation function. Finally, some simulation results are presented to verify theoretical derivations.
